

US Visa Prediction Using Python

The **US Visa Prediction** project aims to develop a **machine learning model using Python** to predict whether a visa application will be **approved or denied** based on applicant information and historical visa data.

Many visa applications are processed every year, making manual evaluation time-consuming and complex. This project analyzes factors such as applicant details, education, experience, job information, and other relevant attributes to identify patterns that influence visa approval decisions.

By applying **data preprocessing, exploratory data analysis, and machine learning techniques**, the system helps improve prediction accuracy and supports faster and data-driven decision-making.
